

## Properties of Chemicals

- Recall that intermolecular forces are the attractive forces that exist between entire molecules
- The state of a pure substance (solid, liquid, or gas) depends on the strength of the intermolecular forces
  - The particles in a solid are very tightly packed together indicating a strong intermolecular force between particles.
  - Whereas the particle in a gas are so far apart (because they move in all directions at great speeds), the intermolecular forces between particles is almost insignificant
- Recall, that the melting point is the temperature at which a substance changes from a solid to a liquid. The boiling point is the temperature at which a substances changes from a liquid to a gas.
  - When chemicals melt or boil, the intermolecular forces between the molecules are being overcome and broken

Solid

particles held firmly in place  
∴ strong intermolecular forces

Liquid

weaker intermolecular forces as particles can slide past each other

Gas

weakest intermolecular forces as particles are so spaced out from each other

- \* The melting and boiling points of different chemicals are indicators to the strength of attraction between molecules (ie. strength of intermolecular forces)
  - o In order to predict the relative ranking of melting and boiling points of different chemicals, we need to know the strengths of the different intermolecular forces

- \* o Remember when comparing the strength of London dispersion forces, the bigger molecule (ie. the one with more electrons) will have stronger London dispersion forces
 

↓  
total e<sup>-</sup>, not just valence e<sup>-</sup>
- Conductivity is another physical property that can distinguish between ionic and molecular compounds
  - o Conductivity is the ability of a substance to conduct electrical charge (or a substances ability to allow an electrical current to flow)
  - o Electrical current is the directional flow of electrons or ions
- \* • Solid ionic compounds have valence electrons that are held solidly in place; therefore they cannot conduct electricity
  - o However, since ionic compounds are made of ions, when dissolve in water the ions are able to move past one another allowing them to carry an electrical current
- \* • Most molecular compounds cannot conduct an electrical current because they are not made up of ions and also the valence electrons are not free to move through the molecule

## Practice Problems

1. Chloroform,  $\text{CHCl}_3(l)$ , has the same shape as methane,  $\text{CH}_4(g)$ . The boiling point of methane is  $-182^\circ\text{C}$  and the boiling point of chloroform is  $61^\circ\text{C}$ . Explain this difference.

$\text{CHCl}_3$  has a higher boiling point b/c it is not a symmetrical tetrahedral shape like  $\text{CH}_4$ .  
 $\therefore \text{CHCl}_3$  will have dipole-dipole forces rather than just London (dispersion) forces that are present in  $\text{CH}_4$ .

2. List the following substances in order of increasing boiling points:  $\text{C}_2\text{H}_5\text{OH}$ ,  $\text{SiO}_2$ ,

$\text{C}_3\text{H}_8$   
 $\downarrow$   
 nonpolar  
 = London (dispersion)  
 forces only

$(6e^-) \times 3 + (1e^-) \times 8$   
 $= 24e^-$

$\text{O} - \text{Si} - \text{O} \therefore$  nonpolar as well

$1(14e^-) + 2(8e^-) = \text{London (dispersion) forces only}$   
 $= 30e^-$

$\therefore$  stronger

$\downarrow$   
 hydrogen bonding  
 $\therefore$  highest boiling point

$\text{C}_3\text{H}_8$	low
$\text{SiO}_2$	$\downarrow$
$\text{C}_2\text{H}_5\text{OH}$	high

3. Use bonding theory (ie. strengths of intermolecular forces) to explain why glycerol,  $\text{C}_3\text{H}_5(\text{OH})_3(l)$ , flows much slower than water,  $\text{H}_2\text{O}(l)$ .

3 places to make a hydrogen bond  
 $\therefore$  molecules have a much stronger attraction to each other than water and cannot slide by each other as easily.

4. Predict which substances will have the higher boiling point in each of the following pairs. Explain your predictions.

a.  $\text{NH}_2\text{Cl}$  or  $\text{PH}_2\text{F}$

has  $\downarrow$  hydrogen bonding vs. dipole-dipole forces present in  $\text{PH}_2\text{F}$

b.  $\text{CH}_3\text{OH}$  or  $\text{C}_2\text{H}_5\text{NH}_2$

both have hydrogen bonding but  $\text{CH}_3\text{OH}$  will have higher boiling point b/c great  $\Delta\text{EN}$  b/w  $\text{O}-\text{H}$  vs.  $\text{N}-\text{H}$

c.  $\text{CH}_3\text{F}$  or  $\text{F}_2$

has  $\downarrow$  dipole-dipole force b/c molecule is not symmetrical  $\therefore$  making it polar.  
 $\text{F}_2$  only has London (dispersion) forces b/c it is nonpolar

d.  $\text{AlCl}_3$  or  $\text{PH}_3$

$\downarrow$   
 ionic compound vs.  $\text{PH}_3$  which is molecular

e.  $\text{NH}_3$  or  $\text{PH}_3$

↓  
has hydrogen-bonding  
vs.  $\text{PH}_3$  which has  
dipole-dipole forces

f.  $\text{C}_4\text{H}_{10}$  or  $\text{Cl}_2$

both are nonpolar  
and  $\therefore$  only have London  
(dispersion) forces, but  
 $\text{C}_4\text{H}_{10}$  is a bigger molecule  
= greater forces

g. neon or krypton

both only have London  
(dispersion) forces, but  
krypton is bigger (i.e. has  
more  $e^-$ )  $\therefore$  has stronger  
forces

h. KCl or  $\text{ICl}$

↓  
ionic compound vs.  
 $\text{ICl}$  which is molecular

i.  $\text{C}_2\text{F}_2$  or  $\text{C}_2\text{HCl}$

$\text{C}_2\text{HCl}$  is a polar molecule  
and  $\therefore$  has dipole-dipole forces

$\text{C}_2\text{F}_2$  is nonpolar and only  
has London (dispersion)  
forces

j.  $\text{C}_2\text{H}_5\text{F}$  or  $\text{CH}_3\text{Cl}$

both molecules are unsymmetrical,  
making them polar with dipole-  
dipole forces. But C-F has a  
greater  $\Delta EN$  than C-Cl  $\therefore$   
giving  $\text{C}_2\text{H}_5\text{F}$  a higher boiling  
point

k.  $\text{NaCl}$  or  $\text{CO}$

↓  
ionic compound vs  $\text{CO}$   
which is molecular

l.  $\text{NH}_3$  or  $\text{CH}_4$

↓  
has hydrogen-bonding  
vs.  $\text{CH}_4$  which is nonpolar  
and only has London  
(dispersion) forces
